as of December 1, 1954

### GENERAL CROP REPORT AS OF DECEMBER 1, 1954

Harvest of late-growing crops was mostly completed by December 1, as a result of favorable to ideal weather for field work in most areas. Corn picking was largely completed, except that in part of the area from Michigan and northern Indiana eastward, wet fields had delayed harvest and ears were a little high in moisture content. About 92 percent of the cotton crop had been ginned, compared with the usual 88 percent by December 1. Soybean harvest is virtually complete after some earlier delays. The extended open fall weather supplied favorable to ideal conditions for hara vesting sorghums, potatoes, sweetpotatoes, rice, peanuts, sugar beets and seed crops, while harvest of sugarcane was proceeding rapidly despite flattening of cane by high winds. For citrus crops, about 8 percent mare oranges, but learngrapefruit and lemons than last season are in prospect,

Varied progress was made with fall work during November, depending upon local conditions. In the wet northeastern area, inability to remove corn and soybeans as early as usual had delayed field preparation and seeding of winter wheat and barley in fields after those crops, possibly limiting seedings to less acreage than intended. Seeding was delayed in the Southeast also, but by dry soils. In most other areas, fail plowing, seeding and most other fall work had made usual to advanced progress.

Fall-scwn grains were mostly in thrifty condition, except in dry parts of the Great Plains area, In the Texas-Oklahoma wheat area, much dryland wheat is in a precarious position, with some deterioration and urgent need of moisture. Some intended acreage awaited rain before seeding is completed, while grazing of wheat is limited to the most favored and irrigated sections. Kansas wheat came up to good stands but has largely used up surface moisture a begun to decline in condition. Livestock were being taken off wheat pastures because of limited replacement growth and probable damage to dry fields. Nebraska wheat was flourishing, but as in all the central and northern Great Plains and in Missouri, rain is needed to condition fields for wintering. In most other areas, the favorable November weather fostered development of even the late planted fields, while in the Pacific Northwest the wheat situation is ideal. Fall sown pasture and hay craps, legumes and grains other than wheat were generally in satisfactory condition.

Pastures continued to furnish some forage and the extended mild weather permitted grazing of harvested fields. Corn fields, in particular, afforded much feed from both stalks and dropped or broken ears. Such gleanings were rather heavy this year as a result of borer damage, heavy winds and delays in harvesting. This source of feed limited demands upon stored feeds and provided hay for movement to drought areas. In the South, pastures were poor following the summer drought, but were improving. Fall-sown grains were providing less than the usual amount of grazing. In western range areas, the mild November weather permitted full

CROP REPORT AGRICULTURAL MARKETING BERVICE

CROP REPORTING BOARD

Washington, D. C. Documber 10, 1954

as of December 1, 1954 3:00 FaMa(E.S.T.)

use of range pastures, with light snow or rain improving palatability of the dried grasses in northern portions. However, the southern and western Great Plains area continues droughty with poor range feed and supplemental feeding is general.

Milk production in November exceeded by a small margin the record set in November 1953, and was a tenth above average. Contributing factors were the mild fall weather, liberal feeding of concentrates, and contra-seasonal increases between November 1 and December 1 in the proportion of cows being milked. The ll-month total of milk production-115 billion pounds--indicates a record annual output is likely in 1954.

Egg production in November, for the 9th successive year exceeded that of the previous November and was 41 percent above average. The rate of lay continued for the 11th year to set a new record for the month. The laying flock was 3 percent Harger than a year ago and 2 percent above average. But potential layers numbered about the same as a year ago, while holdings of pullets not of laying age were smallest in 18 years of record.

CITRUS: Early and midseason oranges for the 1954-55 season are estimated at 71 million boxes -- 2 million boxes less than the November estimate but 7 percent above last season and 36 percent above average. Valencia oranges are forecast at 65 million boxes -- 9 percent above last season and 1b percent above average. The total grapefruit crop is indicated at 46 million boxes -- 5 percent below the 1953-54 crop and 8 percent below average. California lemons are forecast at 16,6 million boxes -- 9 percent below last season but 17 percent above average.

Prospects for the Florida orange crop declined about 5 percent during November, Valencias dropped more than early oranges. Early and midseason oranges are now indicated a little above last season while Valencias are a little below. Grapefruit prospects in Florida are uncharged from a month earlier and the indicated crop is 13 percent below 1953-54 production, Moisture is needed in all areas but the shortage is not yet critical. Cool weather has hastened maturity, improved the color of the fruit, and helped to conserve the limited supplies of soil moisture. Total utilization to date is considerably below a year ago. Fresh use totals about the same but processing has been running below last year.

Growing conditions in Texas continued favorable during November. Trees are in exceptionally fine condition, Quality of fruit is excellent and sizes are satisfactory. Movement was slow during most of November but was increasing by December 1.

Arizona citrus prospects continue favorable. Trees are in good condition and fruit has sized well. Movement is well underway for both grapefruit and nevel oranges.

California weather has been generally satisfactory for the development of citrus crope, Most citrus areas received beneficial rains during November and temperatures have not varied far from normal, Wavels are moving in volume from the San Joaquin Valley. Prospects are well above last season for both navel and Valencia oranges but lower for lemons, Grapsfruit are indicated about the same as last season;

CROP REPORT

CROP REPORTING BOARD

Washington, D. C. December 10, 1954

3:00 P.M. (E.S.T

as of December 1, 1954

> MILK PRODUCTION: November milk production, estimated at 8.4 billion pounds, was only a little above last year's previous record for the month, but was nearly 10 percent above the 1943-52 November average. Mild, open weather in most areas encouraged late use of pasture feed where available, and farmers supplied their milk cows liberally with concentrates as the barn feeding season got underway. Production in November was sufficient to provide each person in the United States with 1.71 pounds of milk per day --- a little less than last November, and about 2 percent less than average. For the first 11 months of 1954, milk production amounted to 115 billion pounds and the total for this year will approach 124 billion pounds if production in December continues close to last year's level.

> Milk production per cow in herds kept by crop reporters rose slightly from November 1 to December 1 this year, and on the latter date averaged 15.89 pounds. The increase was not quite so great as a year ago, but contrasts with an average decline of 2 percent during the month. Regionally, milk production per cow on December 1 ranged from 14 to 21 percent above average and from 1 to 5 percent above a year earlier. The proportion of milk cows in production gained contra-seasonally from November 1 to December 1, closely following last year's pattern but at a slightly higher level. On December 1, 68.0 percent of the milk cows were being milked, the highest proportion for the date in more than a dozen years.

AGRICULTURAL MARKETING SERVICE

CROP REPORT as of CROP REPORTING BOARD December 1, 1954

Washington, D. C. December 10, 195 3:00 P.M. (E.S.T.

7.00 r #1.00 New high records for November were set in 13 of the 33 States for which monthly milk production estimates are available. Production was generally higher than a year ago along the central Atlantic Seaboard, in the Great Lakes area east of Minnesota, in the central South, in the extreme northern Great Plains, and on the Pacific Coast. On the other hand, output was less than in November a year ago in Minnesota, Iowa, South Dakota, Nebraska, Illinois, Virginia, Georgia Virginia, Georgia, Alabama, and Idaho. Wisconsin, with November farm milk production totaling more than one billion pounds, was first among the States, followed by California and Minnesota, each with a little more than one-half billion pounds.

GRAIN AND OTHER CONCENTRATES FED TO MILK COWS: Early winter grain and concentrate feeding rates con-Crop reporters were feeding an tinued heavy in most sections of the country. average of 5.58 pounds of grain and concentrates per cow in herd on December 1, just short of last year's record high of 5.66 pounds for the date, but 9 percent above average for the date, Nationally, the average grain ration being fed on December 1 was up only about one-fourth from October 1 as compared to a usual seasonal increase of one-third. Mild, open weather over most of the country generally permitted full utilization of available fall forage feed. About 85 percent of the crop reporters were feeding some grain or other concentrates to cows in their milking herds on December 1, somewhat below the percentage for that date in the last 2 years, but still above average.

By regions, grain and concentrate feeding rates set a new record high for December 1 in the South Atlantic and equaled the 1952-53 high for the date in the South Central region. In the North Atlantic area, December 1 grain feeding was 1 percent short of the high for the date, and in the other regions the amounts fed by crop reporters were down 5 to 7 percent below the December 1 record rate. Only 5 States, Maine, Maryland, Virginia, Georgia, and Oklahoma recorded new highs this year in the amount of grain and concentrates being fed on December 1. Grain feeding rates were sharply above average in the South, with the amount per cow in the South Central region up 24 percent, and in the South Atlantic region 11 percent, as compared with 4 to 6 percent increases in the other regions.

Grain and concentrate rations fed to milk cows in milk-selling areas in November were valued at \$3.24 per hundredweight, the lowest for the month in 4 years, In cream selling areas the value was \$2.84 per hundredwright, the lowest for the month in the last 5 years. However, prices farmers were receiving for dairy products were at relatively lower levels. The November 1954 milk-feed price ratio was the second lowest for the month since 1936. The butterfat-feed price ratio was the lowest in 18 years.

POULTRY AND EGG PRODUCTION: Farm flocks laid 5,057 million eggs during November, a new high for the month, -- 6 percent more than in November last year and 41 percent above the 1943-52 average. Egg production was at record high levels in all parts of the country. Increases from last year were 12 percent in the West, 7 percent in the East North Central, 6 percent in the West North Central, 5 percent in the South Atlantic and 3 percent in the North Atlantic and South Central States. Total egg

production during the first 11 months of this year for the country as a whole was 59,088 million eggs -- 5 percent more than in 1953 and 12 percent above average.

The rate of egg production in November was 13.0 eggs per layer, compared with 12.8 last year and the average of 9.5 eggs. A record high November rate of lay has been established in each of the last 11 years from 7.5 eggs in 1944 to 13.0 in 1954. The rate of lay was at record high levels in all parts of the country. Increases in the rate from last year were 5 percent in the West and South Atlantic and 2 percent in the North Central States. In the North Atlantic and South Central States, the rate was less than 1 percent above the previous record high of last year. Rate per layer on hand during the first 11 months of this year was 170 eggs, compared with 169 last year and the average of 151 eggs.

The Nation's laying flock averaged about 388 million layers in November -- 3 percent more than in November last year and 2 percent above the average. Number of layers were at record high levels in the North Atlantic, East North Central and the West and were above last year in all parts of the country. Increases from last year were 6 percent in the West, 5 percent in the East North Central, 4 percent in the West North Central, 2 percent in the North Atlantic and South Central and 1 percent in the South Atlantic States. The seasonal increase in layers from November 1 to December 1 was 2 percent, compared with 5 percent last year and the average of 6 percent.

AGRICULTURAL MARKETING SERVICE CROP REPORT

CROP REPORTING BOARD

Washington, D. C. December 10, 195

as of December 1, 1954 3:00 P.M. (E.S.T.

Potential layers (hens and pullets of laying age plus pullets not of laying age) on farms December 1 totaled 430 million -- about the same as a year ago, but 6 percent below the average. Holdings were 4 percent above a year ago in the West, 1 percent below in the North Atlantic and South Atlantic and about the same in the rest of the country.

There were about 39 million pullets not of laying age on farms December 1, the smallest number in 18 years of record, -- 16 percent less than on December 1 a year ago and 45 percent below the average. Holdings were below those of a year ago in all parts of the country. Decreases from a year ago were 28 percent in the East North Central, 23 percent in the West North Central, 13 percent in the West, 10 percent in the North Atlantic and South Atlantic and 8 percent in the South Central States.

Prices received by producers for eggs in mid-November averaged 33.9 cents per dozen, compared with 32.4 cents in mid-October and 49.7 cents a year ago and the average of 49,8 cents, Shell egg markets were irregular in November. Prices were highly sensitive and closed lower on large eggs. Supplice of fresh eggs during the month were ample to burdensome, with receivers anxious to keep receipts moving. Egg receipts at Eastern and Pacific Coast Primary Markets were consistently above last year.

Farmers received an average of 17.7 cents per pound live weight for chickens (farm chickens and commercial broilers) in mid-November, compared with 23.5 a year ago and the average of 25.7 cents. Farm chickens averaged 14.6 cents and commercial broilers 20.3 cents, compared with 20.8 and 26.0 cents, respectively, a year ago. Poultry markets were irregular during the month. Demand for broilers or fryers was weak and prices declined 2 to 5 cents a pound in the major producing areas. Supplies were plentiful and freely offered. Hens were steady to firm and moderately higher during the month. Roaster, capens and other heavy poultry were steady to firm due to the holiday demand.

Turkey prices on November 15 averaged 28.8 cents per pound live weight, compared with 33.9 cents a year ago and the average of 35.6 cents. Turkeys were steady to firm with prices well sustained. Prices were practically uniform throughout the country. Supplies generally were ample to liberal. Ready-to-cook prices varied from 39 cents a pound on the large sizes to 53 - 57 cents per pound for the most part on smaller sizes.

The average cost of the farm poultry ration in mid-November was \$3.78 per 100 pounds, compared with \$3.68 a year ago and the average of \$3.58. The egg-feed, farm chicken-feed and turkey-feed price relationships were all less favorable than a year ago.

Time Defforse

#### ACREAGE AND PRODUCTION OF CROPS IN 1954

One of the larger volumes of crops was produced in 1954, despite acreage restrictions for several important crops and severe drought in a large part of the country, Harvest is now practically completed, with rapid progress under favorable to ideal conditions in November. Most products are of high quality.

All-crop production in 1954 totals over 100 percent of the high 1947-49 average. This is the fifth-largest of record, almost as large as the 101 percent in 1949, although well below the record 106 percent in 1948. In 1952 and 1953 the indexes were 103 percent.

Harvested acreages of the principal crops totaled 337 million acres. 4.2 million acres less than in 1953. Except for 1951, which it barely tops, this is the smallest total since 1941, Yields per acre, however, ranged rather uniformly high for most crops, so that the composite yield index is 107.7 percent of the new 1947-49 base, virtually equalling the record 107.8 set in 1948.

In attaining the large 1954 all-crop volume, only a few crops set new records -- soybeans, rice, sugar beets and oranges. But outturns of cats, barley, sorghum grain, sorghum silage, alfalfa seed, cranberries and commercial vegetables for fresh market as a group, were near = record, Larger than average crops were harvested for rye, flaxseed, cotton lint and cottonseed, all hay, dry beans, tobacco, sugarcane for sugar and seed, olives, lemons, avocados, almonds, walnuts and commercial vegetables for processing as a group. All others were below average in volume, with peanuts and sweetpotatoes a little more than half-average, buckwheat, sorgo sirup and cowpeas less than half-average, velvetbeans about one-fifth and durum wheat less than one-sixth average,

Fall-sown grains were seeded under mostly unfavorable, droughty conditions in the fall of 1953, with much seeding delayed until rains in late October and November improved field conditions. Growers finally completed seeding about all their intended acreage of winter wheat, but under the acreage allotment program it was the smallest acreage seeded since 1943. Continuing drought in the Southwest caused heavy abandonment of wheat, but in other areas all grains wintered well, Spring grains and flax were seeded under favorable conditions in most all but the northernmost sections where a severe cold wave and snow delayed work. More than usual difficulty was met in obtaining stands of cotton and much was late. Corn was mostly planted by June 1, with some delay in a wet northeastern area. Soybeans were virtually all planted by mid-June. For sorghums, planting of the near-record acreage continued over a more extended period than usual, with a large late acreage.

During the spring growing season, crops made good progress except in the dry western portion of the central and southern Great Plains. Even in the dry area some sections favored by light timely rains obtained fair yields of wheat. In most other areas yields were excellent. Spring grains developed well and only a little oats and barley was damaged as harvest approached. However, spring wheat and especially durum, became heavily infested with rust which seriously reduced yields in the Minnesota-Dakotas area, With a general shortage of summer rainfall, drought was a constant threat to crops, but in only a limited area were outturns seriously affected. The dry weather did not affect cotton materially and was favorable for harvesting most grains. Corn was seriously affected in drought areas by searing temperatures at pollination time, resulting in barren stalks usable only for silage or forage. Soybeans weathered the period and recovered to make fair to good yields in most areas. Most other crops struggled along and with a more favorable fall season for growth and maturity developed good outturns, particularly cotton and sorghums. Of the later-growing crops, peanuts were most adversely affected. Tobacco cured out heavier than earlier expected.

Summer drought affected much of the southern half of the country east of the Rocky Mountains. In the Southwest, it was a continuation of the condition that had caused heavy abandonment and low yields of winter wheat. For the third successive summer, Missouri and Arkansas became the center of a drought area which spread in all direction, but mostly eastward during the summer. Most of the area had harvested excellent grain crops and some early hay. But corn was seared at pollinating season, pastures and water supplies dried up and it became evident that feed would be short for livestock. The Southeast was more seriously affected than in 1953. Relief came to much of the area in the fall. Rains in Texas, Oklahoma and up through the Great Plains permitted seeding of wheat, but did not continue in sufficient volume to maintain normal development. November rains appear to have broken the drought in the Southeast, with crop usually relied upon for fall and winter grazing now developing slowly

Record yieldsper acre were realized in 1954 for only cotton lint. barley, all tobacco (particularly burley) and alfalfa seed. Yields of winter wheat, rice, potatoes, sugar beets and hops were second-highest of record, while others nearing top yields include oats, all hay and sugarcane for sugar and seed. Much better than average yields developed for rye, dry beans, cranberries and alsike clover seed, while those for corn, buckwheat, popcorn, sorghum grain, dry peas, soybeans, peanuts, maple products, red-clover and sweetclover seeds, also were above average. On the other hand, yieldsof spring wheat, flaxseed, sorghum for age and silage, cowpeas, sweetpotatoes, sorgo sirup, sugarcane sirup, broomcorn, lespedeza and timothy seeds ranged from near average to sharply below and durum wheat yielded less than a third of average, With most crops yielding above average to record high, the all-crop yield index is computed at nearly 107.7 percent of the 1947-49 base. This is virtually the same as the record set in 1948.

About 354 million acres of the 59 principal crops were planted or grown in 1954. This is nearly 6 million acres less than in 1953 and 5 million below average. It reflects reductions of over 22 million acres in wheat and cotton mostly because of acreage allotments, but these were offset in part, by sharp increases in oats, barley, sorghums, flax, rye, and rices

A relatively small total of 337 million acres of crops were harvested in 1954. Among major crops, there were reductions below 1953 of 0.7 million acres of corn, about 8.2 million acres of winter wheat, 5.8 million acres of spring wheat, 5.2 million acres of cotton and 1.2 million acres of hay. These were partly offset by increases in harvested acreages of oats, 2.9 million acres; barley, 4.4 million; rye, 0.3 million; flax, 1.2 million; sorghum for grain 4.6 million for silage and forage another 0.8 million; and soybears for beans, 2.4 million acres.

By regions, total harvested acreages in 195% were smaller than in 1953 in all but the South Central area. In North Atlantic States, a reduction of over 1 percent lowered the total to 15 million acres, smallest of record. The North Central area total was virtually as large as last year, the 196.7 million acres making up 58 percent of the national total. The 23.4 million acres harvested in South Atlantic States is 5 percent less than in 1953 and the smallest in 26 years of comparable record, reflecting effects of the summer drought. In the South Central area, the large sorghum acreage held the total at 63.6 million acres, slightly above the relatively low 1953 level. In the West, a drop of 7 percent brought the total down to 38.2 million acres. California alone harvested a record total acreage of crops.

Losses of acreage—the difference between planted and harvested totals were about 17.1 million acres. This is 1.5 million acres less than in 1953, but with the added exception of 26 million acres in 1951, the largest acreage loss total since 1939. Most of the 1954 acreage loss was due to 7.4 million acres of winter wheat not harvested for grain, and diversion of 5.1 million acres of oats and 1.5 million of barley, heavier than usual loss of 2 million acres of corn and abandonment of over 2 million acres of sorghums. Not all the diverted acreages of grains is included in the losses, however, as about 3 million acres were harvested for grain hay.

Over 154 million tons of the 8 grains were harvested in 1954. This tonnage was exceeded in 6 of the last 8 years, but in several of these, as in 1953, by only a small margin. The 32.8 million tons of food grains in this year's total has been exceeded in all recent years except 1951, but is more than in any year before 1944. The all wheat outturn of 970 million bushels is nearly 200 million less than in 1953. The rice crop of 58.9 million bags of rough rice continues the record-breaking of each successive recent year, with 6.2 million bags more than in 1953. The 23.7 million bushels of rye is a little above the average of the last 10 years. But the 2.7 million bushels of buckwheat is the smallest outturn in 66 yearsof record.

Feed grain tonnage is relatively large in 1954. The 121.6 million tons was exceeded slightly in 1946 and 1950, otherwise only by the record of 135.4 million tons in 1948. The 2,965 million corn crop is slightly below average, one of 3 in the last 9 years to fall below 3 billion bushels, but it is mostly of good quality and feeding value, outside the drought area. The 1.5 billion bushels of cats, only slightly less than the record 1945 crop, are mostly of good quality and heavy test weight. The barley crop of 370 million bushels is also second-largest in history. Sorghums were planted over a larger period than usual and on-a near-record acreage, often in hopes of obtaining needed forage in drought areas. But favorable growing periods and an extended fall for maturing resulted in much more grain being produced than expected earlier. The outcome was 204 million

Crop Reporting Board, AMS, USDA

ANNUAL CROP SUMMARY, December 1954

bushels of sorghum grain, also a near-record quantity. This total feed tonnage, together with heavy carryover stocks, provides a record total supply and a near-record supply per animal unit for the 1954-55 feeding season.

While the 104,4 million tons of mostly good quality hay is lol million tons less than in 1953, it is 2.4 million tons more than average. With the average carryover, it would provide an ample supply if well distributed, but shortages are likely in areas affected by the 1954 summer drought, and where much hay has been fed to supplement poor grazing. A record proportion and tonnage of alfalfa and alfalfa mixtures and more grain hay were harvested, but relatively small amounts of clover-timothy and lespedeza hay and less wild hay and other kinds than in 1953.

Oilseeds will be in record supply in 1954-55, with a total of ever 17.5 million tons. This is about 6 percent more than in 1953 and a fourth more than average. The record 343 million bushel scybean crop makes up nearly 60 percent of the total. The expected 5.6 million tons of cottonseed is a tenth more than average, but makes up less than a third of the total. With only 1,044million pounds of peanuts the tonnage is a little more than half average. But the fourth-largest flaxseed crop of 41.5 million bushels helps swell the total.

Tobacco acreage barely exceeded that of 1953 and was below average because of restrictions on some types, but with a record yield of 1,337 pounds per acre production of all types totaled 2,200 million pounds, a total exceeded only 3 times previously. As in some previous dry seasons, the leaf weighed out heavier than expected.

Nearly 2.6 million tons of sugar, raw value, may be produced from beets and cane this year, compared with over 2.4 million tons last season. With an expanded acreage of sugar beets and a near-record yield, a record 14 million tons were produced. The outturn of 6,940,000 tons of sugar-cane for sugar and seed is 9 percent less than the record 1953 crop. Production of sugar cane sirup is less than a third of average and of sorgo sirup about 40 percent of average; each is less than in 1953. With a favorable season and more trees tapped, more maple products were produced, especially sirup, than in 1953.

Potatoes were grown on an 8 percent smaller aceage than in 1953, but with a near-record yield. The outturn of 355 million bushels was 7 percent less than last year and an eighth below average. Production of early potatoes was sharply curtailed with an acreage a fifth less than in 1953. The reduction in the late crop was less percentagewise, but larger in bushels. Fall rains and the extended growing season increased yields over earlier prospects. The 30 million bushels of sweetpotatoes is the third smallest crop since 1881. Yields were record high in New Jersey, but limited by drought in southern areas.

Ory beans were grown on an acreage nearly a fifth larger than in 1953, but abandonment was heavy. Yields were adversely affected by wet weather in the Northeast area and by drought in the Southwest; in

addition, clean-out was heavy. Production of 18,9 million bags (thresher run) or 17 million bags (clean basis) is above average, For dry peas, acreage, yield and production were all slightly larger than in 1953, but the 3.5 million bags is less than two-thirds of average, Production of 1,359,000 bushels of cowpeas for dry peas was the smallest in 31 years of record, Velvetbeans continued the downtrend to a production of 68,000 ton, less than a fifth of average.

The supply (1954 production plus-carry-ever) of the six important haycrop seeds -- alfalfa, red, alsike and sweetclover, lespedeza, and timothy -for planting during the 1954-55 season is 7 percent smaller than a year earlier and 11 percent below average. Smaller carry overs into 1954 of each of these seeds, except alsike clover, more than offset the slightly larger total production. Harvesting began a little late, but went forward mostly under favorable conditions. Quality of the 1954 crop of these seeds is fairly good to goode

Production of the major deciduous fruits totaled 8,3 million tons in 1954, about the same as in 1953, but 8 percent below average. The apple crop was 11 percent larger than in 1953, but slightly below average. Most of the increase was in the East, despite some loss from the hurricane. Production was less than last season in the Central area, but slightly larger in the West. Compared with last season, crops of peaches, grapes, plums, apricots, sour cherries and cranberries were smaller, but outturns of pears, prunes, figs, sweet cherries, olives and avocados were largere Only sweet cherries, cranberries, olives and avocados made larger than average crops. The 1954-55 citrus crops are forecast at 8.5 million tons-3 percent more than the 1953-54 total and a sixth above average. In all citrus areas, growing conditions have been favorable this season. The current orange crop will be record high, but grapefruit outturns are forecast a little below last season and average, while the lemon crop will be smaller than last season, but above average. Tree mits stotaled 173,000 tons--17 percent less than in 1953 and 6 percent below average. Pecan production dropped to less than half that of 1953, which more than offset increases in almonds, walnuts and filberts,

Of the 28 vegetables grown commercially for fresh market, about 10,175,000 tons were produced in the 1954 season. This is only I percent less than the record tonnage in 1953 and 6 percent above average. Only in the spring season did the tonnage exceed that of the comparable season last year. More snap beans, cantaloups, celery, sweet corn, cucumbers, escarole, green peppers, tomatows and watermelons were produced than in 1953. Less asparagus, broccoli, Brussels sprouts, cauliflower, spinach, and particularly cabbage and onions more than offset the increases. Of the ll vegetables for processing-commercial canning, freezing, pickling and other uses-about 5.95 million tons were produced in 1954. This is 10 percent less than in 1953, but 4 percent more than average. The 1.74 million acres from which these were harvested was less than in 1953 and below average. Outturns of green peas for canning and freezing, spinach and tomatoes for processing were relatively low, but snap beans for processing were a record large crop. This year's production was valued at about 244 million dollars, compared with 277 million in 1953 and the average of 225 million. Wisconsin leads in acreage of processing vegetables, but California leads in production and value.

The 1954 corn crop missed the 3 billion bushel level attained in 8 of the past 12 years. Production of all corn is estimated at 2,965 million bushels, nearly 3 percent under average, and 7 percent below last year. Hot, dry weather over much of the southwestern Corn Belt and the South seared corn at the usual time for pollination. reduced grain yields and led to much acreage being utilized for silage and forage in these areas. Acreage for grain, at 69,084,000, is about 3 percent under 1953 and production of 2,652 million bushels of grain corn is nearly 8 percent less. Plantings of 81,9 million acres were slightly above last year and surpassed July expectations.

A total of 79.9 million acres of corn was harvested for all purposes, 1 percent less than in 1953 and nearly 7 percent below average. A decrease of over 1.5 million acres from last year in the West North Central and South Atlantic States more than offset small increases in other regions. Of this year's total harvested acreage, 69.1 million acres were harvested for grain, 6.8 million for silage, and 4.0 million cut for forage, hogged down or grazed. Last year, farmers harvested 71.2 million acres for grain, 5.9 million for silage and 3.5 million for forage and other purposes, Actual abandonment this year slightly exceeded 2 million acres, or 2.5 percent of the planted acreage. This compares with only 1,4 percent a year ago,

A final yield of 37.1 bushels per acre is indicated for 1954, slightly higher than the November 1 forecast. Although less than the 39.6 bushels last year, it is 1.4 bushels above average. Yields were under last year in all geographic regions except the North Atlantic States. Greatest declines were in the South Central and Southeastern sections of the country. Corn was especially hard hit by the hot, dry weather in June and July. Many fields were complete grain failures; others were poorly filled. Pollination was hindered by the long period of extreme heat and intense sunshine during the tasseling period. Missouri corn, with an average yield of only 16,5 bushels per acre, less than one-half average, was probably most severely affected by the mid-summer drought, but crops in South Carolina, Georgia, Alabama and Arkansas were also severely damaged. On the other hand, a record high yield of 62 bushels was set in Ohio, and several of the other important Corn Belt States produced yields well above average.

Production in the North Central States -- the Cornbelt -- reached a little more than 2.4 billion bushels, or about 82 percent of the national crop. This is nearly 6 percent under 1953. Decreased acreage harvested in the important States of Iowa, Illinois and Nebraska offset. minor increases elsewhere in the Belt. Yields were off sharply in the southern part of the area. This combined with the decline from last year of about 4 percent in harvested acreage led to the lower production. Spring planting weather was generally favorable, but as the season progressed dry weather in the southern part of the area began taking its toll. Corn in a belt across southern parts of Indiana and Illinois. Missouri and southeastern Kansas was damaged badly, leading to considerably more than the usual acreage being utilized for silage and forage. Late August rains fell over most of the area, but were too late to help a large part of the crop. Most northern areas had favorable fall weather and only a negligible portion of the crop failed to mature properly. Fall rains delayed harvest in a number of the northern States in October. Picking lagged until November, but then ideal weather permitted the bulk of the crop to be harvested by the first of December. Ear moisture was low enough in most areas to allow cribbing as soon as harvest got under way.

In addition to general shortages of moisture and high temperatures in the South, several States in the West report some damage due to lack of timely rains. The Northeast had ample rainfall, but suffered some loss in harvesting due to heavy rains and wind damage by the October hurricane.

ALL WHEAT: Production of all wheat in 1954 fell below a billion bushels for the second time in the last 11 years. This year's crop, grown under acreage allotments and marketing quotas, is estimated at 970 million bushels. This is 17 percent smaller than the 1953 crop of 1,169 million bushels and 14 percent smaller than the average of 1,122 million bushels.

A total of about 62 million acres was seeded to wheat in the fall of 1953 and the spring of 1954. This was nearly 17 million acres less than the 78.7 million acres seeded for the 1953 crop and about 11 million acres less than average. Abandonment and diversion in 1954 amounted to 13.3 percent or 8.3 million acres, compared with 14.1 percent or 11.1 million acres in 1953. Total acreage of wheat harvested for grain in 1954 was 53.7 million acres, about one-fifth below last year and average. Winter wheat acreage harvested for grain in 1954 was about 21/2 times as large as that for spring wheat, The all wheat yield of 18.1 bushels per acre in 1954 is 1.1 bushels above average and compares with 17.3 bushels in 1953.

WINTER WHEAT: Production of winter wheat this year, on an acreage sharply curtailed under the allotment program, is estimated at 791 million bushels. This is about 91 million bushels or 10 percent less than last year, but only 5 percent below average. The yield per harvested acre was the second highest of record, offsetting to a considerable extent the reduction in acreage.

An estimated 46,084,000 acres were seeded for 1954 harvest--19 percent smaller than seedings for the previous year's crop and 13 percent less than average. Much of the acreage, particularly in eastern Corn Belt and Atlantic States, was seeded under unfavorable moisture conditions. Germination was late and plants made little growth before December 1. The winter, however, was mild with several good snow covers and the crop in these States came through to harvest with little loss of acreage. In contrast, parts of the southwestern and western plains areas had surface moisture for starting the crop, but extreme drought throughout the remainder of the season resulted in heavy abandonment of acreage. Loss of acreage was again very heavy in western parts of Texas, Oklahoma, Kansas and Nebraska and in New Mexico and Colorado. For the United States as a whole, 16,2 percent of the seeded acreage was not harvested for grain, compared with 17.9 percent in 1953 and the average of 11.9 percent. Harvested acreage totaled 38,636,000 acres, about 8,2 million acres or one sixth less than in 1953 and the average.

For the country as a whole, the yield per harvested acre was 20.5 bushels. compared with 18.8 bushels in 1953 and the average of 17.7 bushels. It was exceeded only by the record yield of 20.9 bushels harvested in 1952. Yields were above average in all major winter wheat States except Texas, Colorado and New Mexico. Record high yields per acre were harvested in most Atlantic coast States, and in Indiana, Illinois, Michigan, Missouri, Kentucky and Washington. In these States, exceptionally favorable conditions from late April until harvest resulted in remarkable recovery from a poor start. In Kansas, the leading winter wheat State the growing season was extremely variable with record yields in the eastern part of the State and low yields and heavy loss of acreage in western areas. In the eastern two thirds of the State, precipitation was timely and conditions were near ideal for filling and maturing much better than average yields of high test weight. Stem rust damage to winter wheat was limited largely to later wheat in Nebraska and South Dakota.

The 179 million bushels of all spring wheat harvested ALL SPRING WHEATS in 1954 is the smallest crop since the drought year of 1936, except for 1939. It is only five-eighths as large as 1953 and average. A decline of 28 percent in harvested acreage from a year earlier accounts for most of the decrease, but lower yields than in 1953 and average also were a factor. Spring wheat acreages show the sharpest decline from a year earlier in the far Northwest. In 1953, spring wheat acreage in this area was expanded because winter wheat seedings in the fall of 1952 were limited by dry weather. In 1954, early season conditions for spring wheat were generally favorable. But black stem rust and some periods of hot, dry weather lowered yield prospects in most States, especially in the important producing area of the Dakotas, Montana and Minnesota, with durum production most affected. A total of 15.1 million acres of all spring wheat was harvested, compared with 20.8 million acres in 1953 and the average of 19.3 million acres. The yield of all spring wheat averaged 11.9 bushels per harvested acre. compared with 13.8 bushels in 1953 and the average of 15.0 bushels.

OTHER SPRING WHEAT: Production of spring wheat other than durum in 1954 is estimated at 173,487,000 bushels, the smallest in 15 years. It is 37 percent less than the 1953 production and 31 percent below average. The 13,749,000 acres harvested in 1954 is over one-fourth less than in 1953 and nearly one-fifth below average. The sharpest declines in acreage from last year occurred in Idaho, Washington and Oregon, where relatively large adreages of spring wheat were harvested in 1953. Yield per harvested acre for the U. S. as a whole was 12.6 bushels, compared with 14.5 bushels in 1953 and the average of 15.2 bushels.

Plantings were generally completed without delay and the crop had a favorable start in most producing areas. A heavy infestation of black stem rust in the Dakotas, Minnesota and northeastern Montana lowered yields. Dry, hot weather during July in these areas and the remainder of Montana with some extremely high temperatures also contributed to lower than average yields. Harvest operations were delayed by wet weather in

northern producing areas with some losses in quality as well as yield. The four leading states in production of spring wheat other than durum --North Dakota, Montana, South Dakota and Idaho -- accounted for 84 percent of the U. S. total.

The 1954 durum production was the smallest since separate DURUM WHEAT: estimates for this crop were started in 1919. Production is estimated at only 5,557,000 bushels, compared with the 1953 crop of 12,967,000 bushels and the average of 35,486,000 bushels. This is the third year of relatively low durum output, with a combined 3-year production of about 41 million bushels. which is only slightly larger than an average crop for one year. Other years of low production were 1934 with 6,235,000 bushels and 1936 when the crop totaled 8,113,000 bushels. The peak production was in 1928 with 95,266,000 bushels.

The small crop this year was due to less acreage and sharply lowered yields per acre because of black stem rust and drought. While the area planted to durum has been declining since 1949, acreage cuts have been sharp the past few years due to the threat of rust. The 1.327.000 acres harvested this year were 29 percent less than in 1953 and the smallest of record except for 1934. The estimated yield of 4.2 bushels per harvested acre is the lowest of record and compares with 7.0 bushels for 1953 and the average of 13.9 bushels. With an estimated 1.658,000 acres planted, the loss or abandonment of acreage was 20 percent, the largest since 1936 when 56.6 percent of the acreage was abandoned.

The crop started out favorably with ample moisture for germination. Additional rains during May resulted in a lush growth, but some loss of acreage occurred from flooding of fields during June in North Dakota along the Canadian border. A heavy infestation of black stem rust (race 15b) and dry weather later in the season heavily damaged the crop and caused many fields to be abandoned. Yields per acre were low in all durum growing States, with lowest yields in the heart of the durum section. Test weights were below standard throughout the entire durum area and much of the crop is too light for milling.

The Nation's crop of oats is estimated at 1.500 million bushels. This is nearly one-fourth more than the production in 1953, oneseventh more than the 10-year average, and the second largest crop of record. Fall seeded oats came through last year's mild winter in good condition and matured mostly in advance of the hot weather. Crops from these fall seedings represent a larger than usual portion of the total production as yields were unusually good in the Atlantic and South Central States, and in southern areas of several North Central States.

Oats seedings for all purposes, made during the fall of 1953 through spring 1954, are estimated at 47.3 million acres. This is 8 percent above a year ago and the largest of record. A part of this increase is attributed to an attempt by growers to replemish stocks of oats for feeding purposes. However, the bulk of the increase represents acreage diverted from crops placed

under allotments. In the Scuth Central and South Atlantic regions where there was great need for winter and spring pasturage, seedings were increased by one-third and one-tenth, respectively. With somewhat more oats cut for hay and silage, and some unusual losses by hurricane winds, the portion of the J. S. seedings harvested for grain, at 89.1 percent is nearly 1 point smaller than usual. The harvested acreage, now estimated at 42.2 million acres, is 7 percent above last year and, with the exception of 1946, is the largest harvested acreage in 28 years.

The U. S. yield of 35.6 bushels per acre is 4.8 and 2.3 bushels larger, respectively, than 1953 and the average. Good to excellent yields were harvested from a larger than usual acreage of fall seeded oats. More extensive use of improved and adapted varieties, and the application of more fertilizer were contributing factors. The growing season for oats was the most favorable in three years,

In the North Central region, which has nearly four-fifths of the U. S. crop, yields in 11 of the 12 States were higher this year than last, but yields in 4 States were below average. Good to excellent yields were harvested in the South Central and Atlantic areas northward to Pennsylvania. However, a combination of several detrimental factors reduced yields of late oats below early season expectations. Chief amoung these are the rust in Wisconsin, Minnesota, Iowa and the Dakotas; excessively high temperatures, which forced premature ripening in northern areas; and hurricane winds and rain which lodged and shattered late cats in some New England areas. Despite the wide variety of conditions under which the crop was produced, quality of this year's crop is one of the best in recent years.

BARLEY: The 1954 barley crop totaled 370 million bushels. This compares with last year's crop of 243 million bushels and the 10-year average of 275 million bushels. Production this year was the second largest of record, being exceeded only by the 429 million bushel crop in 1942. The increase in production over last year was due to a larger acreage harvested and a record high yield per acre.

Acreages were increased in virtually all barley producing States, with sharpest increases in the Corn Belt and winter wheat area, partly replacing allotment crops. In the major barley States, the acreage harvested was up 133 percent in Montana, 46 percent in North Dakota. 23 percent in California, and 10 percent in Minnesota. Of the 14,517,000 acres planted to barley, about 10.5 percent was abandoned or diverted to other uses, leaving 12,994,000 acres for harvest as grain. This compares with 8,586,000 acres harvested in 1953 and the record of 16,958,000 acres in 1942.

Barley yield set a new high record of 28.5 bushels per harvested acre. Last year 28.2 bushels were obtained and the average is 25.3 bushels. Yields were generally better than last year and also above average along the Atlantic coast and in East North-Central States. Weather conditions were satisfactory early in the season in West North Central States, but hot, dry weather later in the season damaged the crop. In California, the leading barley State, the season was very favorable with a record high yield per acre, largely because of heavy yields on fields diverted from cotton. In North Dakota, which ranks second, the yield was above average but lower than in 1953. Some loss of weight and grade resulted from prolonged rains at harvest time in northern Red River Valley sections of North Dakota, and Minnesota. In Montana, the third most important barley State, yields varied considerably, but were generally low in eastern section. These three leading States accounted for 46 percent of the U.S. total production.

RYE: Rye production in 195h is estimated at 23,688,000 bushels, 30 percent cent larger than in 1953 and 7 percent above average. The 1,718,000 acres harvested this year are about one-fourth larger than in 1953, but nearly a tenth less than average. The current yield per harvested acre was 13.8 bushels, slightly above last year and nearly 2 bushels above average. An estimated 4.0 million acres were planted to rye for the 1954 crop, compared with 3.3 million acres planted for the 1953 crop.

About 43 percent of the rye acreage planted for 1954 was harvested for grain, a slightly larger percentage than in 1953. Most of the acreage diverted from grain was used for pasture, hay, cover crop or plowed under as a green manure crop. North Dakota production is estimated at 4.5 million bushels, one-fourth larger than a year earlier and nearly 19 percent of the U.S. total. South Dakota again ranks second, even though its production of about 2.5 million bushels was one-sixth less than in 1953. Illinois, with a production of nearly 2.1 million bushels, over three times that of 1953, ranks third.

Seedings in the fall of 1953 were made under unfavorable dry conditions in many areas; however, late fall rains provided sufficient moisture for germination. These were followed by early spring and summer rains, resulting in rye yields above average in nearly all areas except the far Northwest. Record high yields per acre were recorded in Illinois, Indiana, Missouri, Ohio, and States to the east. Increased interest developed in rye as a substitute crop for wheat, which was under acreage allotments and marketing quotas. Drought conditions in the southern Great Plains States limited the supply of pasture and forage in late 1953, consequently considerable rye was sown in that area last fall for grazing purposes.

BUCKWHEAT: Production of buckwheat during 1954 continued the downward trend which began in 1948. This year's buckwheat crop, estimated at 2,719,000 bushels, is the smallest crop in 89 years of record, and 15 percent below the 3,193,000 bushels harvested in 1953. The yield of 18.2 bushels per harvested acre is the same as in 1953 and slightly above the average yield of 17.4 bushels. The estimated 149,000 acres harvested in 1954 represent a decline of 15 percent from a year earlier, and is smallest of record, while the 175,000 acres planted to buckwheat was down 7 percent. Abandonment of acreage was larger than in 1953 and the average.

ANNUAL CROP SUMMARY, December 1954 Crop Reporting Board, AMS, USDA

Heather factors were a major cause of the reduced buckwheat production in 1954. Hurricane Hazel, which struck in mid-October, damaged many fields in western and central New York, the leading State in the production of buckwheat. Pennsylvania, the second most important State, had hot, dry weather during planting time, which reduced the acreage planted. Weather conditions throughout the remainder of the buckwheat producing area were generally favorable for planting spring sown crops, thus reducing the need for a "catch-crop," such as buckwheat. Better than average yields per acre were recorded in all areas except Tennessee, New York, and Maine.

RICE: The 1954 production of rice is estimated at 58.9 million equivalent 100-pound bags of rough rice. This record large crop is
12 percent more than the 52.6 bags produced in 1953 and about 59 percent more than the average. Record large crops were harvested in each of the four Southern rice producing States, but the California crop was the smallest since 1951.

Rice was harvested from an estimated 2,405,000 acres in 1954 -- the largest acreage of record. This is 13 percent more than the 2,129,000 acres harvested in 1953 and about 42 percent more than average. A larger acreage than last year was harvested in each producing State, with increases of 55 percent in Mississippi, 23 percent in Arkansas, 8 percent in both Louisiana and Texas, and 10 percent in California. Yield per acre averaged 2,447 pounds -- 24 pounds less than the record high 1953 yield of 2,471 pounds, but 275 pounds above average. Substantially higher yields per acre than in 1953 were obtained in Mississippi, Arkansas and Louisiana. In Texas, the yield was slightly lower than last year, while the yield in California was reduced rather sharply due to the unfavorable growing conditions. The abandoned acreage, estimated at 2,3 percent, was about the same percentage of planted acreage as last year.

Rice production in the Southern area -- Mississippi, Arkansas, Louisiana and Texas -- totaled almost 48 million bags, compared with about 40.4 million bags in 1953. Record large crops developed in each of these States as rice grew and was harvested under very favorable conditions.

In California, a record large acreage was also seeded, but estimated production of about 10.9 million bags was about 11 percent less than the 12.3 million bags harvested in 1953. Due principally to the continued cool weather during July, August and September, much of the rice never developed satisfactorily. This resulted in a larger than usual abandonment of acreage and the lowest yield per harvested acre since 1925.

COTTON: A 1954 cotton crop of 13,569,000 bales is estimated based on information as of December 1. This is 363,000 bales, or 2.7 percent above the November 1 forecast and compares with the 1953 crop of 16,465,000 bales and the average of 12,448,000 bales.

The acreage of cotton in cultivation on July 1 is estimated at 19,776,000 acres, 1 percent less than was estimated in July 1954 and compares with the 1953 acreage of 25,244,000. The 1943-52 average is

22,428,000 acres. Abandonment of acreage in cultivation July 1, including acreage removed to comply with acreage allotments, is estimated at 3.0 percent, leaving 19.187,000 acres for harvest. This compares with 19,285,000 acres as estimated in September 1954 and 24,341,000 acres in 1953.

The average lint yield per acre of 339 pounds for the United States is the highest of record, 15 pounds above the previous record-high yield of 1953, and compares with the average of 272.1 pounds. Yields are less than average in the Carolinas, considerably above average in Central States, and sharply above average in irrigated areas of Texas and the West.

April weather was especially favorable for planting throughout the Belt; cotton germinated rapidly and made good growth. In the Central Belt and Piedmont area of the eastern States, frosts in early May followed by below average temperatures killed or stunted plants. The percentage of the crop replanted in these areas was probably in excess of any other year. The replanted cotton came up rapidly despite continued cool weather during May. With rainfall less than average in May and June, the crop around July was in an excellent state of cultivation, and was making exceptionally good progress. Moisture reserves were below average.

In contrast to conditions during the last several seasons, soil moisture was adequate for planting the intended acreage in Texas. Stands were generally satisfactory and growth and recovery from a late start were particularly good in northern and western districts. Drought conditions, however, were again developing in a wide belt of Texas, covering most of eastern and southeastern Texas, the central and southern Blacklands and extending to other counties. In California, Arizona, and New Mexico, stands and early season advancement were very good, June weather was favorable but moisture supplies were becoming short toward the end of the month.

In most Central and Eastern areas, July weather continued dry and not, but fruiting made good progress. August rainfall with the exception of the first few days, consisted of only limited scattered showers and shedding was excessive particularly in the last two weeks of the month, Sizing of bolls was checked and premature opening became general, especially in late cotton. Continued dry weather caused premature ripening of bolls in central, east, and some dryland areas of northwest Texas. In California, Arizona, New Mexico, and irrigated areas of Texas, cotton prospects continued highly favorable.

Scattered showers in some areas during September and general rains in Central States around mid-September, together with some intermittent relief from excessively high temperatures, tended to check deterioration. October and November weather was exceptionally favorable for development of late bolls and the crop in Central and Eastern States turned out much better than expected when droughty conditions were at the peak. In irrigated areas, continued favorable weather through most of November resulted in record to near-record yields in those areas. Meather during the harvesting season was nearly ideal everywhere.

Ginnings were practically completed by December 1 except in irrigated areas. In Texas and New Mexico, about 10 percent of the crop remained to be ginned while around 20 percent of the crop was yet to be ginned in Arizona and California, For the United States, about 92 percent of the crop was ginned by December 1, compared with 87,5 percent a year ago, and the average of 87,8 percent.

HAY: The 104.4 million tons of all hay produced in 1954 is 1.2 million tons below last year's crop. Acreage harvested, at 72.8 million, was the smallest in 5 years, chiefly because of sharp reductions in lespedera and wild hay and somewhat less clover-timothy hay acreage, Extensive drought in South Central and South Atlantic sections reduced hay acreage either through failure to make sufficient growth or by diversion to pasture. Most of the reduction from earlier production prospects resulted from a smaller acreage cut for bay than expected earlier. The U. S. yield of all hay at 1,43 tons per acre is equal to last year and the third highest of record, reflecting the large proportion of acreage in higher yielding hay crops, and the generally satisfactory season in many areas,

New grass and legume seedings of hay crops generally made a favorable early start in the 1954 season with less than usual winter loss of fall seeded acreage. Early hay cuttings were fairly heavy in most areas, although unusually severe attacks occurred from spittlebug, aphis and other insects, prompting extension of spray control measures. Continued increases in the diversion of early hay crop cuttings to grass silage were reported in Northeastern dairy States. Some freeze damage in May and prolonged cool weather retarded alfalfa growth in many North Central areas. July and August drought and heat were other unfavorable factors which for alfalfa were largely offset by good rains which brought on additional growth late in the season,

Distribution of hay production in 1954 is similar to last year, with relatively good crops in North Atlantic and most North Central, Northern and Pacific Coast States, and short crops in South Central, South Atlantic and some Western States, South Central States, as a group, were hardest hit by the arought; production for this region is about oneseventh less than the 1953 tonnage. Many farmers have made adjustments in livestock numbers to face the recurring hay shortage. Mild fall weather has helped stockmen save stored hay by permitting full use of field residues and late pasture and range growth. Total forage is expected to be generally adequate except in sections where summer drought was most severe.

Alfalfa moved ahead again in 1954 among the hay crops in total and relative importance. Nearly half of all hay cut this year consisted of alfalfa or mixtures so considered by growers. The 49.3 million ton crop represents the seventh annual increase in alfalfa tonnage since 1946. Alfalfa acreage expanded about 60 percent during these years, reached leading rank in acreage among the hay crops in 1954 and now makes up almost one-third of the total, Increases over last year occurred in a majority of States. Clover-timethy hay production of 27.6 million tons

was about 8 percent below last year and except for one year is smallest since 1941.

The wild hay crop of 10.2 million tons was 15 percent smaller than in 1953 with smaller crops in most leading States. Grain hay tonnage increases over last year were general in a majority of States, occurring consistently in the South and West, Lespedeza hay outturn was especially disappointing. Drought retarded growth of this late southern hay crop so severely that much potential hay acreage either virtually failed or was used only for pasture, The 3,1 million-ton crop produced this year was about one-fourth less than last year is short crop. Smaller tonnages of scybean, cowpea, peacut and "other" hays were cut or saved this year. Tonnage from these hay classes totaled 7 percent less than in 1953,

ALL SORGHUMS: Production of sorghum grain is estimated at 204 million bushels, almost double the 109,353,000 bushels harvested in 1953 and second only to the 1950 crop of 233 million bushels, Yield per acre on the 10.764,000 acres harvested for grain is 19.0 bushels, compared with 17.8 bushels in 1953 and the average of 18.2 bushels. Droughty conditions caused below average yields for Kansas, Oklahoma, and Colorado. Irrigation of a fairly large percentage of the acreage in Texas, and timely rains on dry lands resulted in per acre yields in that State sufficiently above average to offset reductions in other major producing States,

The 19,882,000 acres planted to sorghums this year is exceeded only by the 21,2 million acres planted in 1940 and is 36 percent greater than last year's 14,651,000 acres. In both Texas and Kansas, the two leading sorghum producing States, record high acreages were seeded. These two States, along with Oklahoma and Colorado, account for 85 percent of the U.S. acreage. The sharp increase in seedings of sorghums for all purposes comes largely on acreage diverted from wheat and cotton by acreage allotments and on acreage where abandonment of wheat was heavy. Also the trend from corn to sorghum grains continues in areas where droughty conditions have existed for a number of years.

Abandonment of 10.3 percent of planted acreage left 17,828,000 acres of sorghums harvested for all purposes (including sirup). Percentage abandonment was quite heavy in Oklahoma, Colorado, and New Mexico where the effects of drought were most severe. In most other States abandonment was comparatively light. Of the total acreage harvested, 60.4 percent was for grain, 32.7 percent for forage and pasture, 6.6 percent for silage, and 0.3 percent for sirup. Last year 49.5 percent was utilized for grain, 42.3 percent for forage and pasture, 7.9 percent

Crop Reporting Board, AMS, USDA

ANNUAL CROP SUMMARY, December 1954

for silage and 0.3 percent for sirup. Comparatively large proportions of this year's acreage in Oklahoma, Colorado and New Mexico were unfit for grain harvest, but in most other States a larger than average percentage of the total was combined. The extended fall season permitted grain on even the late acreage to mature, resulting in considerably more grain than expected earlier.

Acreage utilized for forage, including that pastured, totaled 5,831,000 acres -- 11 percent above last year. Forage production is estimated at 6,431,000 tons, compared with 6,191,000 tons in 1953. The yield of 1.10 tons per acre is slightly below last year's yield of 1.18 tons. Sorghum put in silos this year totaled a near-record 6,890,000 tons, compared with 5,912,000 tons last year. About 1,185,000 acres were cut for silage in 1954 and 979,000 acres in 1953.

POPCORN: Growers in 11 commercial popcorn States produced 222 million pounds of ear popcorn in 1954. This is 31 percent less than the 322 million pounds harvested in 1953, but only 4 percent below the 10-year average of 232 million pounds. About 206 million pounds of the 1954 crop were grown in the 8 Corn Belt States. Output in the other 3 producing States was only about a third as much as in 1953.

The drought made deep inroads into the 1954 crop. Popcorn suffered some damage from hot, dry weather in each State, except possibly Michigan. The more southern areas suffered most, with the crop in Oklahoma and Texas a near failure. Production was below last year in all States except Michigan.

Ohio acreage was 25 percent below 1953, but good yields per acre resulted in a crop of about 26 million pounds of generally good to excellent quality popcorm. Indiana with 55 million pounds, replaced Illinois as the largest producing State. Good yields per acre this year helped to hold up production even though acreage was 30 percent less than in 1953. Illinois, despite drought damage, produced 10 million pounds compared with 58 million in 1953. Iowa growers harvested a larger acreage than in 1953, but low yields per acre cut production to about 43 million pounds, 8 percent below the previous year. High temperatures and dry weather hurt the Misscuri crop--reducing both acreage and yields--resulting in a small crop of only 9 million pounds. Acreage in both Nebraska and Kansas was below 1953. Yields were relatively low in Nebraska but exceeded those of last year in Kansas. Production in Kentucky was only about a third of 1953--because of a 51 percent reduction in acreage and much poorer yields than a year earlier.

Growers in the 11 States planted 147,300 acres in 1954, or 31 percent less than the 214,400 acres planted in 1953. Acreage losses were light except in areas where the drought was most severe. The 1954 harvested acreage of 141,100 acres is 29 percent less than the 198,700 acres harvested in 1953.

Only about three-fourths of the total crop had been harvested by November 1 compared with 93 percent last year by the same date. Wet weather in the eastern Corn Belt States delayed harvest considerably.

The proportion of yellow and white popcorn changed very little from last year. About 83 percent of the 1954 production was yellow popcorn and 17 percent was white. Indications are that about 60 percent of the 1954 crop was grown under contract, a somewhat smaller percentage than for the 1953 crop.

Official estimates are prepared for only 11 States, but an additional 10 to 15 million pounds of popcorn may have been produced in other States, notably Colorado, Idaho, Maryland, Tennessee and Virginia.

DRY BEANS: Dry bean production in 1954 is estimated at 17 million bags (100 pounds clean basis). This compares with 16,8 million bags in 1953 and the 10-year average of 16.2 million bags,

Production of Pinto beans estimated at 4,567,000 bags (clean beans), about 6 percent less than in 1953, far exceeds that of any other class. Pea beans were second with 3,131,000 bags; this is a drop of nearly one-half million bags from 1953. Great Northerns are in third position with about 2 million bags, a gain of about 200,000 bags from last year. Red Kidney production, at 1,219,000 bags, is down slightly from last year, Production of Large and Baby Limas is estimated at 1,259,000 bags and 758,000 bags, respectively, both higher than 1953.

The 1,714,000 acres planted to dry beans in 1954 was nearly a fifth larger than in 1953, but the percentage abandoned also was much higher--8.1 percent in 1954 compared with 2.7 percent in 1953. The indicated yield of 1,199 pounds (uncleaned basis) per harvested acre was over 100 pounds less than in 1953, but still well above the average of 1,037 pounds per acre. All producing areas report lower yields than were harvested in 1953.

The Northeast area had a relatively poor season, especially in Michigan which had one of the most difficult seasons of record. Despite a sharp increase in Michigan planted acreage, production (clean basis) was down one-half million bags from last year. Early in the season, rain drowned out considerable acreage and later on heavy and continued rains hampered harvest. Abandonment of acreage was heavy and in addition clean-out was also far above average. In the Northwest area, yields were generally down from last year. Only Washington showed an increase in yield per acre over 1953. In that State a considerable part of the acreage was planted on new irrigated land. This plus a favorable season resulted in a State yield of 2,170 pounds per acre.

The Southwest (Pinto) States were again severely affected by drought which reduced yields; however, because of increased acreage, production in the area is only a tenth below 1953, California had a favorable season. The State yield of 1,534; pounds was slightly below last year mainly because a larger proportion of the acreage was planted to lower yielding varieties. Large and Baby Lima yields were slightly above last year, but "other beans" were slightly lower.

DRY PEAS: The 1954 dry pea production (excluding Austrian peas) is estimated at 3,077,000 bags (100 pounds, cleaned basis). This is approximately 3 percent more than the 1953 crop of 2,974,000 bags, but smaller than average. Production of Alaskas and other smooth green peas is estimated at 1,482,000 bags (100 pounds, cleaned basis), slightly more than 2 percent above the 1953 crop. The outturn of Canadas and other smooth whites and yellows, at 587,000 bags, is 16 percent less than last year's crop. Production of all other kinds (principally wrinkled peas for seed) is one-fifth larger than in 1953.

The 287,000 acres planted to dry peas in 1954 was 5,000 acres more than last year. Nearly all of the acreage increase occurred in Washington and Idaho, which had 85 percent of the planted acreage in the 9 States for which estimates are made. Abandonment of seeded acreage amounted to 6.6 percent, compared with 7.1 percent in 1953. The estimated 268,000 acres harvested represents a 6,000-acre increase from last year, but is 175,000 acres below average.

The average yield for the 1954 crop, at 1,300 pounds per acre (uncleaned basis), is 21 pounds more than last year, and 62 pounds above average. Yields were better than a year earlier in Washington, the leading dry pea State, and the same as in 1953 in Idaho, the second most important State. The dry pea crop in Washington and Idaho was damaged by frosts and dry weather early in the season. Rains at harvest time resulted in lower quality peas. A shortage of irrigation water in Colorado contributed to a reduction in yield in that State.

SOYBEANS: Soybean production in 1954 is estimated at 343 million bushels, the highest of record. This is 28 percent above the 269 million bushels harvested from the 1953 crop and 15 percent above the previous high of 299 million bushels in 1950. The record production this year comes largely as a result of increased acreage, since the indicated yield of 20.1 bushels per acre is only slightly above the average yield of 19.9 bushels per acre. However, the current yield is well above the relatively low yield of 18.3 bushels per acre harvested last year.

A record total of 19.3 million acres was planted to soybeans in 1954, 15 percent above 1953, the previous high, Of the total acreage, about 17 million acres or 88 percent was harvested for beans. This compares with 14.7 million acres and 87 percent for beans in 1953. The percentage cut for hay was below last year while the acreage for "other purposes", which includes abandomment, was higher than in 1953.

The 1954 crop season was one of sharp contrasts for soybeans. The final outturn showed several States producing record yields, while others reported near failure. Planting was generally completed with little difficulty and moisture supplies were sufficient to bring the crop up to a good stand. July drought brought reports of poor condition over much of the soybean area. However, August rains provided needed moisture over the northern parts of the main Soybelt. In this area, extending across Ohio, most of Indiana, the northern half of Illinois, Iowa and Minnesota,

record and near record yields were harvested. Drought, however, continued over much of the southern producing area and yields in most of the southern States were poor. The crop was nearly harvested by December 1, after considerable delay during October and part of November due to wet weather. Moisture content of the beans harvested has run well above that of the past two years. In some areas, the crop was too wet at harvest time for safe storage.

The North Central States produced 90 percent of the Nation's soybeans, a slightly higher percentage than last year. Record yields for each State were harvested in Ohio, Indiana, Minnesota and Iowa. The Illinois crop'was seriously damaged by drought in the southern half of the State, and while the yield of 21.5 bushels per acre is one bushel above last year, it is over a bushel below the average. Missouri and Kansas were hard hit by the drought, and reported yields were low in both States.

In the South Atlantic States soybeans were damaged by drought, but fair yields were received in all producing States except South Carolina, Georgia and Florida. Yields in those States were well below last year. The South Central States were again hard hit by dry weather after a very poor year in 1953. The area yield of soybeans is only ll.4 bushels per acre, slightly below the very poor yield of 12.4 bushels per acre harvested in 1953. Arkansas, the heaviest producer in the area, had a yield of only ll.5 bushels, compared with the average of 17.0 bushels per acre.

COMPEAS: Production of cowpeas harvested for dry peas in 1954 is estimated at 1,359,000 bushels. This is one-fourth less than last year and the smallest production since records began in 1924. The 10-year average production is 3,065,000 bushels. A yield of 4.9 bushels per acre is indicated this year, compared with 6.1 bushels in 1953 and the average of 5.9 bushels per acre.

The 1,173,000 acres of cowpeas planted for all purposes in 1954 exceeds last year by 132,000 acres, but is still the fourth smallest acreage of record. About 24 percent of the total acreage was harvested for dry peas in 1954 compared with 28 percent in 1953. The percentage cut for hay was also less than a year ago. The season generally was not favorable for cowpeas, as drought reduced yields over a large part of the cowpea producing areas in the southern States.

PEANUTS: The production of peanuts picked and threshed in 1954 is placed at 1,044 million pounds, 34 percent less than last year's 1,588 million pounds and 47 percent below the average. This year's production of 1,044 million pounds is the smallest crop produced since 1934 when 1,014 million pounds were harvested. In 1934, however, 1,514 thousand acres were picked and threshed compared with only 1,368 thousand acres in 1954.

The acreage picked and threshed in 1954 was 11 percent below 1953 and only about one-half of the average acreage picked and threshed. The yield of 763 pounds per acre picked and threshed was 26 percent below last year's record yield of 1,031 pounds per acre, but still 3 percent above the average yield of 742 pounds.

In the Virginia-Carolina area, the 1954 crop was planted under unfavorable conditions and much replanting was necessary. Dry weather throughout much of June retarded growth of the young plants, but enabled growers to thoroughly cultivate their fields. Good rains in July helped the crop to overcome the poor start and with adequate rainfall the rest of the growing season the crop turned out well in this area with per acre yields averaging 1,668 pounds per acre, only 2 percent below last year's yield of 1.695 pounds and well above the average of 1,222 pounds per acre. Production in this area, estimated at 470 million pounds, is 4 percent below last year's production of 492 million pounds.

In the southeastern area, production of peanuts is estimated at 422 million pounds, 47 percent less than the 795 million pounds produced last year and 61 percent below average.

Hot, dry weather during June and July retarded early growth in this area and with drought conditions prevailing over most of the area for the rest of the growing season, the 1954 crop averaged only 594 pounds per acre picked and threshed in contrast with 1953 when yields averaged 966 pounds per acre. The average yield for this area is 746 pounds per acre. An unusually large acreage in this area was harvested for hay without picking and threshing this year. Only about 65 percent of the acreage grown alone this year was picked and threshed compared with the average of about 75 percent picked and threshed.

The crop in the Southwest area was planted under generally favorable conditions and got off to an excellent start, However, hot, dry weather through most of June and July materially retarded the growth of the crop and later rains were not sufficient to overcome the earlier deficiency of moisture. Some growers delayed harvest in the hopes of obtaining improved yields. There was also a considerable diversion of acreage intended for picking and threshing to harvest for hay in this area. The production of 151 million pounds for the Southwest area is only one-half the 1953 crop. The average yield of 402 pounds from the acreage picked and threshed is 43 percent below last year's near record yield of 704 pounds and 15 percent below average.

VELVETBEANS: The 413,000 acres of velvetbeans grown in 1954, although 31 percent more than in 1953, was less than in any other year since records were started in 1924. Acreage of velvetbeans has been trending sharply downward and this year's total is less than half of average. Due to severe drought in the Southeastern States, where practically all of the crop is grown, the 1954 yield of only 329 pounds per acre was about one-half as large as the previous record low of 657 pounds produced in 1952. Nearly two-thirds of the U.S. acreage is grown in Georgia, where the yield this year is estimated at only 220 pounds. Production of velvetbeans in the hull, whether grazed or

harvested otherwise, is estimated at 68,000 tons. This compares with 130,000 tons in 1953 and the average of 367,000 tons.

FLAXSEED: Production of 41.534.000 bushels of flaxseed in 1954 is the fourth largest of record. It exceeds 1953 and average production by about one-eighth. A near record acreage harvested accounts for the relatively large production, since yields per acre averaged the lowest since 1936. The Dakotas and Minnesota account for 93 percent of the U. S. crop, with North Dakota alone producing nearly 25 million bushels -- about three-fifths of the Nation's total.

The estimated 5,663,000 acres harvested in 1954 is second largest in the 65 years of record, barely exceeded by the 5,691,000 acres in 1943. It is one-fourth larger than last year and two-fifths larger than average. The planted acreage totaled nearly 6 million acres, also the second largest of record, For the three principal producing States, harvested acreage compared with last year was up 40 percent in North Dakota and 34 percent in South Dakota, but declined 9 percent in Minnesota. The yield of 7.3 bushels per harvested acre this year is 0.9 bushels below the 1953 yield and 2.0 bushels below average.

Early season weather was generally favorable for seeding and growth in nearly all major flax growing areas. In North Dakota and northern Minnesota, a considerable acreage was seeded late, resulting in a larger acreage than indicated as of July 1. Dry weather in July and early August, with temperatures generally above normal and some extremely high during the first half of July, appear to be the main factors resulting in a decline in production prospects after July 1. Wet weather delayed harvest in the Dakotas and Minnesota and late September frosts did some damage in northern producing areas.

Total tobacco production is estimated at 2,200 million pounds, 7 percent above last year's crop of 2,055 million pounds and the fourth largest of record. Growers harvested 1,645,400 acres in 1954, nearly one percent more than last year. The average yield per acre of 1,337 pounds is 27 pounds higher than the previous record set in 1951.

The 1,334 million pounds of flue-cured tobacco produced this year exceeds the 1953 crop by 5 percent. Only in 1946, 1951 and 1952 has the flue-cured crop been larger. Growers harvested 1,042,200 acres, 2 percent more than in 1953.

Production of Burley is placed at 617 million pounds compared with the November estimate of 582 million pounds and the 564 million pounds produced last year. Although grown on the smallest acreage since 1943 (4 percent below that harvested last year), the crop is the third largest of record. The 1,528 pounds per acre average yield establishes a new record--125 pounds above the previous high in 1952. Despite the dry summer in parts of the Burley belt, timely rains in August and optimum growing and curing conditions the remainder of the season brought about remarkable recovery in most areas.

Maryland tobacco production is estimated at 42.5 million pounds grown on 50,000 acres, Last year 40.5 million pounds were harvested from 45,000 acres.

The 60.5 million pounds of <u>fire-cured</u> tobacco harvested this year compares with 48.9 million pounds produced last year. The <u>dark air-cured</u> crop was harvested from 25,000 acres and at 31.9 million pounds is one-fifth larger than last year's production.

Production of cigar tobaccos is estimated at 114 million pounds, ll million pounds above the 1953 crop. Filler production at 50.7 million pounds is up from last year by one-fourth, For binder types, 47.0 million pounds is estimated, slightly less than last year. The crop of wrappers totaled 16.3 million pounds, 10 percent above 1953. Despite hailstorms and hurricanes, the Connecticut Valley shade crop was only 5 percent below last year, The Georgia-Florida shade crop, however, was nearly  $1\frac{1}{2}$  times the 1953 production.

HAY SEEDS: Hot, dry weather in many sections during the summer of 1954 reduced supplies of forage to such an extent that thousands of acres that normally would have been harvested for seed were cut for hay or were pastured. Although crops in general were affected by the droughty conditions, yields per acre of legume and grass seeds on the acreage harvested were mostly above average. Generally speaking, weather conditions for harvesting were quite favorable, with the result that quality of the 1954 seed crops is fairly good to good.

The 1954 production of alfalfa, red, alsike, and sweetclover, lespedeza, and timothy seed totals 371.1 million pounds of clean seed. This is 1 percent more than in 1953 but 21 percent below the 1943-52 average. Because the carry-over into the 1954 crop was 24 percent smaller than a year earlier, the total supply (1954 production plus carry-over) for planting during the 1954-55 season is 7 percent less than that of the preceding season. The 1954-55 supply is 11 percent below average.

The 1954 crop of alfalfa seed is second largest on record, while the alsike-clover seed crop is the smallest on record, red-clover seed the smallest in 17 years, and lespedeza seed the second smallest in 18 years. Compared with the 1953 crops, red and alsike-clover seed production in 1954 is about a third smaller but production of alfalfa, lespedeza, timothy, and sweetclover is a sixth to a tenth larger.

Acreage and production of each of the six important hay seeds for the <u>United States</u> only appear in this report. But data for these seeds and about 20 others, by <u>States</u>, will be given in a separate seed report on December 20 covering acreage, yield per acre, production, season—average price, and value of production.

MUNG BEAMS: The 1954 production of Mung Beans in Oklahoma, the only State for which this crop is estimated, is 400,000 pounds. This compares with 6,500,000 pounds in 1953 and the 10-year average of approximately 11,000,000 pounds.

Dry weather at planting time resulted in reducing the acreage planted to about 12,000 acres. Continued dry weather throughout the summer caused heavy abandonment, so that only about 4,000 acres were harvested, compared with 20,000 in 1953 and the average of 43,400 acres. Two-thirds of the planted acreage was abandoned this year, which is nearly twice the usual percentage loss. Yield per acre is estimated at only 100 pounds, compared with 325 pounds in 1953 and the average of 260 pounds.

BROOMCORN: The 1954 production of broomcorn brush was the smallest of record despite some boost in output resulting from improved growing conditions in late summer and fall. This year's crop is estimated at 26,900 tons, 13 percent below the 31,000 tons produced in 1953, and nearly one-third smaller than average. Larger crops than in 1953 were produced this year in Texas, New Mexico and Illinois, but production was much smaller in Oklahoma. Colorado and Kansas.

Much of the early broomcorn in western dry-land areas was stunted by the drought and excessive heat, and some plantings failed to produce merchantable brush. Growth was uneven and in some cases only portions of fields were harvested. However, the moisture situation improved somewhat after mid-July and additional plantings, intended for both brush and control of wind erosion were made after the rains. Some of the late plantings reached maturity during the relatively long period of frost-free fall weather. A larger portion than usual of the total tonnage produced was harvested from late plantings, and from broomcorn grown under irrigation.

The planted acreage is estimated at 292,000 acres of which 237,000 acres were harvested. Abandonment of 55,000 acres represented 19 percent of the planted acreage and, except for 1952 and 1953, was the largest in 15 years. In 1953, growers planted 329,000 acres of which 260,000 acres were harvested for brush.

Yields per acre were slightly above average in Illinois and New Mexico, but much below in all other States. Quality of the 1954 crop brush is very poor to good. The U. S. yield of 226 pounds per acre compares with 238 pounds last year and the average of 288 pounds.

HOPS: Production of hops in 1954 is estimated at 43,491,000 pounds—4 percent more than the short crop of 1953 but 19 percent below the 1943—52 average. A total of 27,500 acres was harvested in Idaho. Washing—ton, Oregon & California—about 2 percent less than the 1953 acreage. About 300 acres were left unharvested in both 1953 and 1954 in Oregon, Yields per acre averaged above last year in each of the States except Idaho where yields were spotty. The 1954 average yield of 1,581 pounds per acre for the four States is exceeded only by the record yield of 1,600 pounds in 1952.

COMMERCIAL APPLES: The 1954 commercial apple crop is estimated at 103,773,000 bushels, il percent larger than the 1953 crop but 2 percent below the 1943-52 average. Most of the increase over 1953 is in the Eastern States where production totaled 49,802,000 bushels, 27 percent more than last year and 13 percent above average. These estimates do not include apples lost as a result of the hurricane on October 15 in several eastern apple States and two earlier hurricanes in New England. In the Central States 1954 production totaled 16,276,000 bushels, 8 percent below 1953. The Western States' total of 37,695,000 bushels is 4 percent above last year but 13 percent below average.

Delicious, the leading variety, accounted for about 22 percent of the total commercial crop. Production of McIntosh dropped about 15 percent from 1953 because of a smaller crop in New England. This variety continues in second place with about 10 percent of the total production. Winesaps, Rome Beautys and Jonathans rank next with little change in production from last year. Production of York Imperials, Staymans, Yellow Newtowns, Golden Delicious, Baldwins, Gravensteins and Spys was above last year and average.

Apple production in most of the New England States fell below last year with generally light crops of McIntosh partly offset by heavy crops of the later Baldwin variety. The New York crop of 15,485,000 bushels is more than 2 million bushels larger than last year with increases in all important varieties except R. I. Greening. In the Appalachian area, production was about 60 percent larger than the short 1953 crop and 18 percent above average. With the large crop, many of the apples blown off by the October 15 hurricane were not picked up in this area.

The Michigan crop is down 31 percent from last year and 16 percent from average as a result of cold weather during bloom. The Spy variety, which blooms late, produced a very large crop but other important varieties were down sharply from last year. Conditions were better in Ohio resulting in a crop 24 proent larger than last year. Illinois production was reduced by dry weather which limited size.

Late spring frosts caused spotty damage in the Northwest. The important Washington crop is estimated at 22,700,000 bushels, 7 percent smaller than in 1953 and 20 percent below average. Size and color are not as uniform as usual although overall quality is good. Oregon production is 26 percent above last year's short crop with a good crop of Newtowns in the Hood River area. The California production was 17 percent above last year with an increase of about 41 percent in the early Gravenstein crop.

PEACHES: Production in 1954 totaled 60,794,000 bushels — 6 percent less than in 1953 and 9 percent less than average. California clingstone peaches are estimated at 19,210,000 bushels — 15 percent below last year and 7 percent below average. U.S. production other than California clingstones totaled 41,584,000 bushels — slightly less than in 1953 and about 9 percent below average. California freestone production at 12,084,000 bushels, was 14 percent larger than in 1953 and the largest crop since 1946.

The peach crop in the North Atlantic States is estimated at 5,590,000 bushels - slightly larger than last year and about 9 percent above average. The 1954 crops were above last year and the average in New Jersey and Pennsylvania but below both last year and average in New York.

Production in the South Atlantic States totaled 9,812,000 bushels ---4 percent below last year and 11 percent below average. Hot, dry weather in this area hastened maturity and resulted in small size but quality was generally good. The crop in the South Central States totaled 3,453,000 bushels -- 40 percent below last year and 38 percent below average. Low temperatures in March cut peach production sharply except in Alabama, Kentucky and Tennessee. Alabama production was above both last year and average. The crops in Texas and Oklahoma were near failures and the Arkansas crop was 45 percent below average.

In the North Central States, Michigan production, which continued the downward trend of recent years, was about one-third below average and 16 percent below last year. However, production increased over 1953 in all other States in this group, with the total for the region 3 percent above 1953 but 20 percent below average.

The 1954 crop in Colorado was 70 percent larger than the 1953 crop and the second largest of record. In the Northwest States, late spring freezes cut production below average.

PEARS: The 1954 pear crop is estimated at 30,077,000 bushels, about 3 percent larger than the 1953 crop but slightly below average. The Bartlett pear crop in the three Pacific Coast States totaled 20,193,000 bushels, 17 percent larger than the 1953 crop and 6 percent above average. Production of other pears in these States totaled 5,898,000 bushels -- down 18 percent from last year's large crop and 10 percent below average.

California production of Bartlett pears was a record high of 14,793,000 bushels, up about  $4\frac{1}{2}$  million bushels from last year. In Oregon, freezing weather in late April damaged Bartlett and other pears especially in the Medford area. Production was considerably below average and last year. The spring freeze also damaged pears in Washington, resulting in a light crop of Boscs and spotty production of Anjous.

Michigan pear production was 31 percent less than the large 1953 crop but 26 percent above average. The Bartlett crop was very light in Michigan this year. New York production dropped sharply to 285,000 bushels in 1954, the smallest crop since 1948.

GRAPES: The 1954 grape crop is estimated at 2,607,300 tons, 3 percent less than last year and 12 percent below average. Grape production in California and Arizona totaled 2,373,600 tons, compared with 2,483,100 tons in 1953 and the 1943-52 average of 2,777,350 tons. These two States produce practically all of the European type grapes grown in this country. Production in the other States totaled 233,700 tons, compared with 216,900 tons in 1953.

The 1954 California production of 2,370,000 tons of all varieties was the smallest crop since 1942. California production of wine varieties was up 16 percent from last year, table varieties were up 7 percent but raisin varieties were down 15 percent. Several days of very hot weather in June caused severe sunburn damage to raisin varieties.

Grape production in the Great Lakes States is estimated at 179,000 tons, 19 percent more than last year and 53 percent above average. The crop exceeded earlier expectations in each of the four States -- New York, Pennsylvania, Ohio and Michigan, Most of the grapes in these States are Concords crushed for juice. The Arkansas grape crop was reduced by a freeze in early May and extended drought later in the season. Production was 80 percent larger than the short 1953 crop but 43 percent below average. The Washington crop was 30 percent below the record 1953 crop but 52 percent above average.

CITRUS: Early and midseason oranges for the 1954-55 season were forecast at 71 million boxes as of December 1 -- 2 million boxes less than the November extimate but 7 percent above last season and 36 percent above average. Valencia oranges are forecast at 65 million boxes -- 9 percent above last season and lu percent above average. The total grapefruit crop is indicated at 46 million boxes == 5 percent below the 1953 = 54 crop and 8 percent below average. California lemons are forecast at 14.6 million boxes -- 9 percent below last season but 17 percent above average.

Prospects for the Florida orange crop declined about 5 percent during November. Valencias dropped more than early oranges. Early and midseason oranges as of December 1 were indicated a little above last season while Valencias are a little below. Grapefruit prospects in Florida were unchanged from a month earlier and the indicated crop is 13 percent below 1953-54 production. Moisture is needed in all areas but the shortage is not yet critical. Cool weather hastened maturity, improved the color of the fruit, and helped to conserve the limited supplies of soil moisture. Total utilization to December 1 was considerably below a year earlier, Fresh use totaled about the same but processing has been running below last year,

Grawing conditions in Texas continued favorable during November. Trees are in exceptionally fine condition. Quality of fruit is excellent and sizes are satisfactory. Movement was slow during most of November but was increasing by December 1.

Arizona citrus prospects continue favorable. Trees are in good condition and fruit has sized well. Movement is well underway for both grapefruit and navel oranges.

California weather has been generally satisfactory for the develcpment of citrus crops. Most citrus areas received beneficial rains during November and temperatures have not varied far from normal. Navels are moving in volume from the San Joaquin Valley, Prospects are well above last season for both navel and Valencia oranges but lower for lemons. Grapefruit are indicated about the same as last season,

PLUMS AND PRUNES: Production of plums in California is estimated at 72,000 tons, 16 percent below last year's large crop and 10 percent below average. About 4,000 tons of harvested plums were culled out of the 1954 crop compared with 7,000 tons culled out in 1953. The Michigan plum crop is estimated at 6,000 tons, compared with 6,400 tons in 1953 and the average of 5,310 tons.

California production of dried prunes is estimated at 184,000 tons (dry basis) -- 26 percent above last year and the largest crop since 1947. The 1954 production includes 4,000 tons not utilized under a marketing agreement. Some additional tonnage, not included in production, was lost due to rain damage in late August.

Production of prunes in Idaho, Washington and Oregon totaled 68,000 tons (fresh basis) -- 24 percent less than last year and 39 percent below average. Spring freezes caused severe damage in nearly all areas of these States. Estimated utilization of the total crop in these three States with 1953 comparisons is as follows: fresh sales 25,200 tons, down 45 percent; canned 25,430 tons, up 17 percent; dried 9,900 tons (3,200 tons dry basis), up 15 percent; farm household use 4,670 tons, up 6 percent, Practically all of the 1954 crop was harvested and utilized. In 1953, an estimated 5,550 tons were not harvested and 1,600 tons were culled out

SWEET CHERRIES: The 1954 crop of sweet cherries is estimated at 93,140 tons, slightly larger than last year and the 10-year average. Production fell below last year in each of the Pacific Coast States, totalling 67,900 tons, 8 percent below 1953. Rainy weather during bloom cut the California crop and a freeze at the end of April caused considerable damage in some areas of Washington and Oregon, Utah production was above average after a very short crop in 1953. The Idaho crop of 2,900 tons was near average and more than double the short 1953 crop. Montana production continued an upward trend with a record-large 1954 crop of 2,600 tons.

Production in the Great Lakes States, New York, Pennsylvania, Ohio and Michigan -- totalled 14,690 tons, 12 percent above last year and 51 percent above average, The New York crop of 5,200 tons has been exceeded only by the record crop of 6,000 tons in 1951, The 1954 crop in Michigan fell below last year but was 57 percent above average.

SOUR CHERRIES: Production of sour cherries is estimated at 104,020 tons, 21 percent less than the 1953 crop and 4 percent below the 10-year average, With short crops in Michigan and Wisconsin, production in the Great Lakes States totalled 92.960 tons, 25 percent less than last year and 3 percent below average. Frost in May, followed by a heavy June drop, reduced the Michigan crop to 47,000 tons, the smallest since 1945. Wisconsin production was 11,000 tons compared with the large 1953 crop of 18,500 tons, Conditions were more favorable in New York and Pennsylvania with increases of 12 and 52 percent, respectively, over the 1953 production.

Production of sour cherries in the Western States totalled 11,060 tons, an increase of 39 percent over the short 1953 crop but 9 percent below average. Production was larger than last year in all of the Western States except Oregon, which was 6 percent below last year.

CRANBERRIES: The 1954 crarberry crop is estimated at 1,012,000 barrels-16 percent less than the record 1953 grop of 1,203,300 barrels, but 29 percent above the 1943-52 average. Production was below last year but above average in each of the five States.

In Massachusetts, cool, rainy weather in September delayed harvest resulting in larger size berries than usual. Some berries were more mature than usual when harvested but shrinkage was about average and keeping quality above average, Rainy weather in September also hindered harvest in New Jersey and some bogs were flooded by heavy rains accompanying the hurricanes. In Wisconsin, October weather was favorable for harvesting and quality turned out better than was expected earlier, Washington and Oregon cranberries did not size as well as usual.

APRICOTS: Production of epricots in California, Utah and Washington totalled 144,900 tons--40 percent less than in 1953 and the shortest crop since 1943, California production was 130,000 tons in 1954 and 230,000 tons ir 1953. The set of fruit was light in the important Santa Clara Valley area. Quantities of California apricots sold fresh, dried and used for other processing are all considerably below last year with the heavisst reduction in the tonnage dried. The Washington production of 9,800 tons is 20 percent below last year and about one-half of average. Frosts in late April caused severe damage and resulted in a very spotuy production. Utah production was nearly up to average after a very short crop in 1953

PECANS: Production in the 10 important pecan States is estimated at 92,502,000 pounds-only 44 percent of last year's bumper crop and 69 percent of average, All States share in this sharp decline from last year. Improved varieties total 40,842,000 pounds and seedlings 51,660,000 pounds,

A drought in nearly all of the pecan areas during most of the growing season was the principal cause of the short crops, although spring freezes caused a light set in several sections, Georgia, the most important State in the production of improved pecans, produced a crop only about one-third as large as last year and a little more than half of average. A hard freeze during the Blooming season caused a light set of nuts. In addition, shedding was heavier than usual because of hot dry weather starting the latter part of May. Very little rain was received until after the crop was matured. Nuts are much smaller than usual but the quality is very good otherwise. In Florida, the crop was relatively better in Jefferson County than in other sections.

Texas, the most important State in the production of seedling pecans, harvested a larger crop than expected on October 1 or November 1. However, the production now estimated is a fifth below last year and almost a third below average.

In creek and river bottoms and in irrigated orchards, where moisture was available, yields were fair to good but in other areas, yields were generally very short. The crop was particularly short in southern districts and on the Edwards Plateau. In Oklahoma, production was confined largely to the southern third of the State. Many groves in the central and northeastern sections had failures compared to good crops last year.

ALMONDS, FILBERTS AND WALNUTS: The 1954 almond crop in California is estimated at 43,900 tons, 14 percent larger than last year and second only to the record crop of 47,200 tons in 1946.

Production of filberts in Oregon and Washington totaled 8,650 tons, 74 percent more than the short 1953 crop and 9 percent above the average. The percentage of blanks was above normal although not as high as in 1953.

Walnut production in California and Oregon is estimated at 73,900 tons, 25 percent more than the short 1953 crop and slightly above average. Harvested production fell below earlier expectations in both States. In Oregon, many crops show a high percentage of shrivelled kernels and a smaller than usual proportion of the crop will meet grades for marketing in the shell.

TUNG NUTS: The crop in the 5 producing States of Florida, Georgia, Alabama, Mississippi, and Louisiana is estimated to total 40,200 tone of air-dried nuts in the husk. This is one-third of the large 1953 production and 16 percent below average, Freezes in March caused severa damage to the bloom and set in all States, but particularly in Mississippi and Louisiana. Drought during the growing season further reduced yields. Harvest was underway in October, earlier than usual, but mills have been later than usual in starting operations because of the short crop. Production in Mississippi, usually the leading State, is placed at 16,000 tons-less than one-fourth of last year. Louisiana at 4,000 tons is less than a fifth of last year. Florida, Alabama and Georgia have short crops but relatively better than Mississippi and Louisiana.

AVOCADOS, DATES, FIGS, OLIVES AND PINEAPPLES; The 1954-55 production of avocados in California and Florida is expected to total 44,800 tons, 37 percent more than the 1953-54 crop. All of the increase is in the California crop which is forecast at 34,600 tons compared with 22,200 tons last season. Harvest of the Fuerte avocado crop in California will be at peak during February and March. In Florida, about three-fourths of the crop had been picked by December 1,

The 1954 date crop in California is estimated at 13,500 tons, 13 rercent smaller than the 1953 crop and slightly below the 10-year average.

Production of dried figs in California totaled 24,200 tons, about equal to the 24,300 tons produced last year but 24 percent below average. California production of fresh figs is estimated at 11,000 tons, compared

ANNUAL CROP SUMMARY, December 1954 Crop Reporting Board, AMS, USDA

with 10,000 tons in 1953 and the average of 15,000 tons.

Olive production in California is expected to total 52,000 tons, nearly double the short 1953 crop and 10 percent above average. The set of fruit was spotty with a heavy load on some trees resulting in small average size. Harvest for canning was nearly completed by November 1 and harvest for oil began about mid-December.

The 1954 pineapple crop in Florida is estimated at 25,000 crates compared with 28,000 crates in 1953 and the average of 9,860 crates.

The 1954 total potato production including the early, inter-POTATOES: mediate and late crops, is estimated at 355,099,000 bushels, 7 percent below the 1953 revised production of 380,075,000 bushels and 13 percent below average. The acreage harvested in 1954 was 1,404,700, down 8 percent from the revised estimate of 1,524,600 acres for 1953 and 34 percent below the average of 2,138,300 acres. Yields this year averaged 253 bushels per acre, 4 bushels above 1953 and 51 bushels above average.

The crop in the 29 late States is placed at 287,453,000 bushels, While this is higher than the estimate on November 1, it is 3 percent less than the revised estimate of 296,879,000 bushels for 1953. This is about the same percentage reduction from last year as was indicated by the November 1 report, Larger acreages were harvested in Maine, Wisconsin, North Dakota and Colorado than indicated earlier and this accounts for most of the increase in the production estimate over November 1. The acreage harvested in the late States was 1,065,600 acres, 4 percent below the revised estimate of acreage harvested in 1953. Weather conditions varied considerably by areas during the growing and harvesting season. The rains after September 1 were generally beneficial to the crop and potatoes sized well. Many large-sized potatoes were harvested this year particularly in the eastern and central States. As a result, yields turned out higher than expected earlier in the season. Wet weather during the growing season in Maine and Michigan resulted in above-average blight damage in these States. Rains also delayed harvest and impaired keeping quality in upstate New York, Maine, parts of North Dakota, Minnesota, Wisconsin, and Michigan. As a result, heavier shrinkage than usual is expected in these areas. On Long Island, New York, the heavy rains that accompanied hurricanes Carol and Edna exposed many potatoes to the sun, causing them to green. Consequently the pick-out on the late harvest is much above average. In Idaho, growth was stopped much earlier than usual by general freezes in late September.

In the Tule Lake-Klamath Falls area of Oregon and California, yields were below last year because of the poor growing weather during the late summer months. In Central Oregon and the San Luis Valley of Colorado, weather was ideal for harvest and the quality of the crop in these areas is good,

The production in the 13 early States was 51,931,000 bushels, 21 percent below last year and 16 percent below average. Most of the decline from 1953 is due to smaller acreages harvested in California, Texas, Alabama, Florida and North Carolina. The acreage in the early States, at 239,400 acres, was down 21 percent from last year. Yield per acre for the 1954 crop, at 217 bushels, was practically the same as the 216 bushels harvested in 1953.

In the 7 intermediate States, the production is placed at 15,715,000 bushels, 11 percent below last year and 42 percent below average. The 99,700 agree harvested were down 5,600 acres from the 1953 crop. The decline was accounted for mostly by the smaller acreage in Virginia, Yields averaged 158 bushels in these States, down 10 bushels from last year but 9 bushels above average.

SWEETPOTATOES: The 1954 sweetpotato crop totaled 29,880,000 bushels, 13 percent below the 1953 production of 34,276,000 bushels and 41 percent below average. The 1954 crop was the third smallest crop since 1881, being only slightly larger than the 28,532,000 bushels harvested in 1952 and the 1951 crop of 28,796,000 bushels. The acreage of sweetpotatoes harvested in 1954 was 345,500 acres, 2 percent less than the 1953 acreage and 37 percent below average. Yields this year averaged 86.5 bushels per acre, compared with 97.7 in 1953 and the average of 92.9 bushels.

The 1954 season varied considerably by areas, Louisiana, which has 30 percent of the production this year, received ample rainfall during the growing season in most areas and the yield per acre for the State was about average. In the other southern States, dry weather prevailed throughout most of the growing season and generally low yields were harvested. In New Jersey, Delaware and the Eastern Shore of Maryland and Virginia, the favorable weather after mid-August resulted in good yields. The New Jersey yield was the highest of record. The quality of the 1954 crop was generally good.

SUGAR BEETS: The 1954 crop of sugar beets is estimated at 14,027,000 tons, the largest crop on record, and 16 percent above last year's crop of 12,084,000 tons. A total of 878,000 acres were harvested this year, 18 percent above 1953 and 23 percent greater than the 10-year average. The average yield, at 16.0 tons per acre is only slightly below the reccord yield of 16.2 tons of last year and compares with the average of 13.7 tons. Abandonment of planted acreage at 8.9 percent was considerably greater than last year's abandonment of 6.2 percent, but about the same as that for the 1950 and 1951 crops. Loss of acreage was heaviest this year in the eastern belt States of Ohio, Michigan and Wisconsin where wet fields at harvest time prevented harvest of considerable acreage and in Colorado where lack of water and some frost damage caused the early abandonment of about 30,000 acres, In other States, considerable replanting was necessary due to freeze and wind damage, but ahandonment was generally light.

Production of sugar from this year's crop of sugar beets is expected to total about 2,037,000 tons, raw value, compared with 1,817,000 tons in 1953.

SUGARCANE FOR SUGAR: Production of sugarcane for making sugar from the 1954 mainland sugarcane crop is estimated at 6,555,000 tons, 9 percent smaller than last year's production, but about 9 percent above the 10-year average. The Louisiana crop is estimated at 5,268,000 tons compared with 5,759,000 tons produced for this purpose last year. Production in Florida is estimated at 1,287,000 tons compared with 1,453,000 tons last year. Acreage harvested for sugar was below last year in both States as this crop was under acreage control for the first time since 1941. Sugar production from cane ground and to be ground is expected to total 555,000 tons, raw value, compared with 630,000 tons produced last year,

In Louisiana, the crop developed slowly early in the season with local showers providing sufficient moisture to maintain fairly good growth. The tropical storm which cut across southern Louisiana in late July brought heavy rains to the entire belt with little or no damage from wind. Local showers after this date were sufficient to maintain continued growth and the estimated yield of 20.5 tons per acre is only slightly below 1953 but about 1.5 tons above average. In Florida, where the crop is grown under controlled water conditions, an above average yield of 33.0 tons per acre is estimated for 1954 compared with last year's yield of 32.7 tons per acre.

SUGARCANE SIRUP: Production of sugarcane sirup is estimated at 4,795,000 gallons, 14 percent below last season's production of 5,575,000 gallons and the smallest crop of record. The acreage harvested, which had declined rapidly in recent years, increased this year as a result of larger acreages harvested in both Louisiana and Florida. The average yield of 171 gallons per acre reflects the effect of this year's drought and compares with the yield of 206 gallons last year and the average yield of 185 gallons.

SORGO SIRUP: The 1954 production of sorgo sirup is estimated at 2,699,000 gallons. This is about 1.5 percent smaller than the 1953 output of 2,739,000 gallons, and with the exception of 1952, was the smallest crop of record. An estimated 48,000 acres of sorghum cane was utilized for making the 1954 crop of sirup, compared with 41,000 acres in 1953 and the average of 110,000 acres. Yield per harvested acre was 56 gallons, compared with 67 gallons in 1953. Principally due to the drought, lower yields per acre than in 1953 were reported for all States, except Kentucky.

MAPIE PRODUCTS: Production of maple sirup in 1954 is estimated at 1,730,000 gallons, 38 percent above the 1953 production of 1,254,000 gallons. Maple sugar production, estimated at 168,000 pounds, was 33 percent above the 126,000 pounds produced last year. The number of trees

tapped this year is estimated at 6,786,000, an increase of 2 percent over 1953. This is the first year since 1947 that the number of trees tapped has increased over the previous year.

The 1954 maple season was exceptionally early over the entire maple area and the opening dates for New Hampshire, Vermont, Massachusetts, New York, Pennsylvania and Michigan were the earliest of records going back to 1953. The early season resulted in the sap being frezen and at times virtually brought the production of sirup to a standstill. The 1954 season was also one of the longest on record extending over 50 days in some areas. Although the sugar content of the sap was low, in some cases requiring almost twice as much sap to produce a gallon of sirup as in 1953, the equivalent sugar yields per tree were generally better than in 1953. Yields in Wisconsin and Minnesota were the exception, both States having lower yields than for 1953.

<sup>1/</sup>Acreage partially duplicated.

<sup>2/</sup>Asparagus, lima beans, snap beans, beets, cabbage (sauerkraut), sweet corn, cucumbers, green peas, pimientos, spinach, and tomatoes.

<sup>3/</sup>Principal vegetables grown for fresh market in major producing States included in regular monthly reports, Artichokes, asparagus, lima beans, snap beans, beets, broccoli, brussels sprouts (since 1949), cabbage, cantaloups, carrots, cauliflower, celery, sweet corn (all major States included only since 1949), cucumbers, eggplant, escarole, garlic, Honey Ball Melons, Honey Dew Melons, kale, lettuce, onions, green peas, green peppers, shallots, spinach, tomatoes, and watermelons. Excludes farm gardens. Acreage for harvest, including mature acreage abandoned or only partially harvested because of low prices or other economic factors.

<sup>4/</sup>Totals are for crops shown in preceding columns, omitting alfalfa seed, red clover seed, alsike cover seed, and lespedeza seed. These are included in the count of crops, but the acreage is not included because mostly duplicated in the hay acreage; the acreage of peanut hay, largely duplicated in peanuts picked and threshed, has been deducted. Other crops not included are hops, spelt, hemp, velvetbeans, various legumes and other crops harvested by livestock, minor crops, and fruits and nuts. The acreages shown include some crops harvested in succession from the same land.

<sup>5/</sup>Preceding column plus estimates of acreage planted, and not harvested, as shown in separate table of acreage losses.

I/The acreages shown for winter wheat represent the acres sown in the preceding fall and not harvested, thus including considerable land subsequently planted to other crops. The totals do not show total crop losses chiefly because of the large acreage of hay land which produced nothing except pasturage in some dry seasons.

2/Rice, buckwheat, potatoes, sweetpotatoes, sugar beets, and dry field peas.

3/Excludes grains cut for hay.

1/Production ginned and to be ginned. A 500-15, bale contains about 480 net pounds of lint. 2/Sums of acreage and production for "other States" rounded to thousands for inclusion in United States totals. Estimates for these States, except Kansas where cotton production is insignificant, are shown separately. 3/Included in State and United States totals.

l/Season begins with the bloom of the year shown and ends with the completion of harvest the following year. In California picking usually extends from about Oct. 1 to Dec. 31 of the following year. In other States the season begins about Oct. 1 and ends in early summer, except for Florida limes, harvest of which usually starts about April 1. Estimates of production include fruit consumed on farms, sold locally, and used for manufacturing purposes, as well as that shipped. Fruit ripened on the trees but destroyed by freezing or storms prior to picking is not included. 2/For economic abandonment, see page 92. 3/The indicated production for 1954 is based on reported prospects on December 1. 4/Includes small quantities of tangerines. 5/Short-time average. 6/Net content of box varies. In Calif. and Arizona the approximate average for oranges is 77 lb. and grapefruit 65 lb. in the Desert Valleys; 68 lb. for California grapefruit in other areas, in Florida and other States, oranges, including tangerines, 90 lb. and grapefruit 80 lb.; California lemons, 79 lb.; Florida limes, 80 lb. 7/In California and Arizona, Navels and miscellaneous.
